

DATE:4-6-24

ASSIGNMENT - 2

11. Container With Most Water

You are given an integer array **height** of length **n**. There are **n** vertical lines drawn such that the two endpoints of the **i**th line are **(i, 0)** and **(i, height[i])**.

Find two lines that together with the x-axis form a container, such that the container contains the most water.

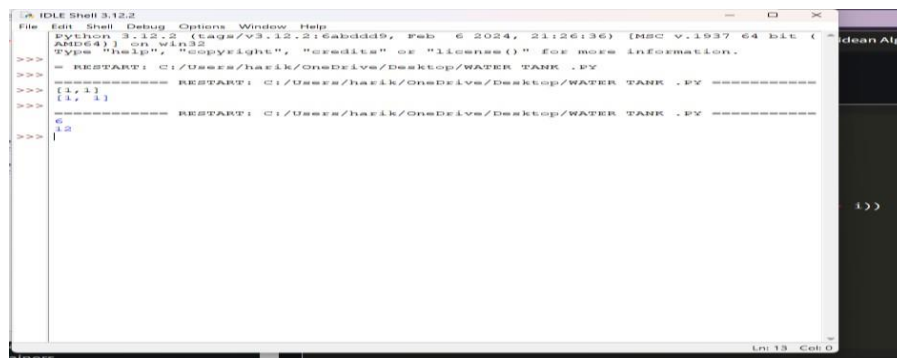

Return *the maximum amount of water a container can store*.

Notice that you may not slant the container.

CODE:

```
def maxArea(A, Len) :  
    area = 0  
    for i in range(Len) :  
        for j in range(i + 1, Len) :  
            # Calculating the max area  
            area = max(area, min(A[j], A[i]) * (j - i))  
    return area  
  
# Driver code  
a = [ 1, 5, 4, 3 ]  
b = [ 3, 1, 2, 4, 5 ]  
len1 = len(a)  
print(maxArea(a, len1))  
len2 = len(b)  
print(maxArea(b, len2))
```

```

12. Roman numerals are represented by seven different symbols: I, V, X, L, C, D and M.

Symbol Value

I 1

V 5

X 10

L 50

C 100

D 500

M 1000

For example, 2 is written as **II** in Roman numeral, just two one's added together. 12 is written as

XII, which is simply **X + II**. The number 27 is written as **XXVII**, which is **XX + V + II**.

Roman numerals are usually written largest to smallest from left to right. However, the numeral

for four is not **IIII**. Instead, the number four is written as **IV**. Because the one is before the five

we subtract it making four. The same principle applies to the number nine, which is written as

IX. There are six instances where subtraction is used:

- **I** can be placed before **V** (5) and **X** (10) to make 4 and 9.
- **X** can be placed before **L** (50) and **C** (100) to make 40 and 90.
- **C** can be placed before **D** (500) and **M** (1000) to make 400 and 900.

Given an integer, convert it to a roman numeral.

CODE:

```
def value(r):
```

```
    if (r == 'I'):
```

```
        return 1
```

```
    if (r == 'V'):
```

```
        return 5
```

```
    if (r == 'X'):
```

```
        return 10
```

```
    if (r == 'L'):
```

```
        return 50
```

```
    if (r == 'C'):
```

```
        return 100
```

```
    if (r == 'D'):
```

```

return 500
if (r == 'M'):
return 1000
return -1
def romanToDecimal(str):
res = 0
i = 0
while (i < len(str)):
# Getting value of symbol s[i]
s1 = value(str[i])
if (i + 1 < len(str)):
# Getting value of symbol s[i + 1]
s2 = value(str[i + 1])

13. Roman to Integer

Roman numerals are represented by seven different symbols: **I, V, X, L, C, D** and **M**.

Symbol Value

I 1

V 5

X 10

L 50

C 100

D 500

M 1000

For example, **2** is written as **II** in Roman numeral, just two ones added together. **12** is written as

XII, which is simply **X + II**. The number **27** is written as **XXVII**, which is **XX + V + II**.

Roman numerals are usually written largest to smallest from left to right. However, the numeral

for four is not **IIII**. Instead, the number four is written as **IV**. Because the one is before the five

we subtract it making four. The same principle applies to the number nine, which is written as

IX. There are six instances where subtraction is used:

- **I** can be placed before **V** (5) and **X** (10) to make 4 and 9.
- **X** can be placed before **L** (50) and **C** (100) to make 40 and 90.
- **C** can be placed before **D** (500) and **M** (1000) to make 400 and 900.

Code:

```
roman = {'I':1,'V':5,'X':10,'L':50,'C':100,'D':500,'M':1000}
```

```
class Solution:
```

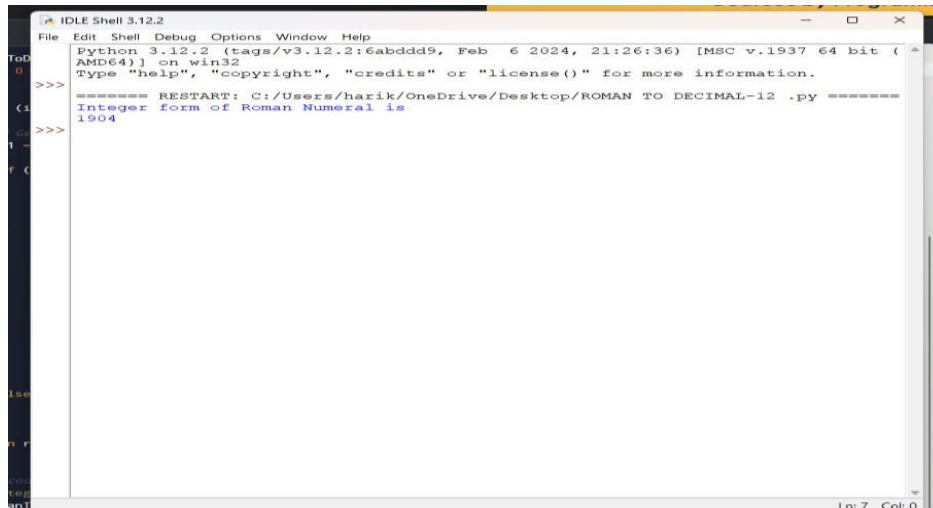

```
def romanToInt(self, S: str) -> int:
```

```
    summ= 0
```

```

for i in range(len(S)-1,-1,-1):
    num = roman[S[i]]
    if 3*num < summ:
        summ = summ-num
    else:
        summ = summ+num
return sum

14. Longest Common Prefix

Write a function to find the longest common prefix string amongst an array of strings. If there is no common prefix, return an empty string ""

CODE:

```

def longestCommonPrefix( a):

    size = len(a)

    # if size is 0, return empty string
    if (size == 0):
        return ""

    if (size == 1):
        return a[0]

    # sort the array of strings
    a.sort()

    # find the minimum length from
    # first and last string
    end = min(len(a[0]), len(a[size - 1]))

    # find the common prefix between

```

```

# the first and last string
i = 0
while (i < end and
a[0][i] == a[size - 1][i]):
i += 1

pre = a[0][0: i]
return pre

# Driver Code
if __name__ == "__main__":

input = ["geeksforgeeks", "geeks",
"geek", "geezer"]
print("The longest Common Prefix is :",
longestCommonPrefix(inp)

```

OUTPUT:

15. 3Sum

Given an integer array `nums`, return all the triplets `[nums[i], nums[j], nums[k]]` such that $i \neq j$, i

$\neq k$, and $j \neq k$, and $nums[i] + nums[j] + nums[k] == 0$.

Notice that the solution set must not contain duplicate triplets.

Example 1:

Input: `nums = [-1,0,1,2,-1,-4]`

Output: `[[-1,-1,2],[-1,0,1]]`

Explanation:

$nums[0] + nums[1] + nums[2] = (-1) + 0 + 1 = 0$.

$nums[1] + nums[2] + nums[4] = 0 + 1 + (-1) = 0$.

$nums[0] + nums[3] + nums[4] = (-1) + 2 + (-1) = 0$.

The distinct triplets are `[-1,0,1]` and `[-1,-1,2]`.

Notice that the order of the output and the order of the triplets does not matter.

CODE:

```
def findTriplets(nums, n, Sum):  
    i = 0  
    j = 0  
    k = 0  
    # list to store all unique triplets.  
    triplet = []  
    # list to store already found triplets  
    # to avoid duplication.  
    uniqTriplets = []  
    # Variable used to hold triplet  
    # converted to string form.  
    temp = ""  
    # Variable used to store current  
    # triplet which is stored in vector  
    # if it is unique.  
    newTriplet = [0, 0, 0]  
    # Sort the input array.  
    nums.sort()  
    # Iterate over the array from the  
    # start and consider it as the  
    # first element.  
    for i in range(n - 2):  
        # index of the first element in  
        # the remaining elements.  
        j = i + 1  
        # index of the last element.  
        k = n - 1  
  
        while(j < k):  
  
            # If sum of triplet is equal to
```

```

# given value, then check if
# this triplet is unique or not.
# To check uniqueness, convert
# triplet to string form and
# then check if this string is
# present in set or not. If
# triplet is unique, then store
# it in list.
if(nums[i] + nums[j] + nums[k] == Sum):
    temp = str(nums[i]) + ":" + str(nums[j]) + ":" + str(nums[k])
    if temp not in uniqTriplets:
        uniqTriplets.append(temp)
        newTriplet[0] = nums[i]
        newTriplet[1] = nums[j]
        newTriplet[2] = nums[k]
        triplet.append(newTriplet)
        newTriplet = [0, 0, 0]

# Increment the first index
# and decrement the last
# index of remaining elements.
j += 1
k -= 1

# If sum is greater than given
# value then to reduce sum
# decrement the last index.
elif(nums[i] + nums[j] + nums[k] > Sum):
    k -= 1

# If sum is less than given value
# then to increase sum increment

```

```

# the first index of remaining
# elements.

else:
    j += 1
# If no unique triplet is found, then
# return 0.

if(len(triplet) == 0):
    return 0

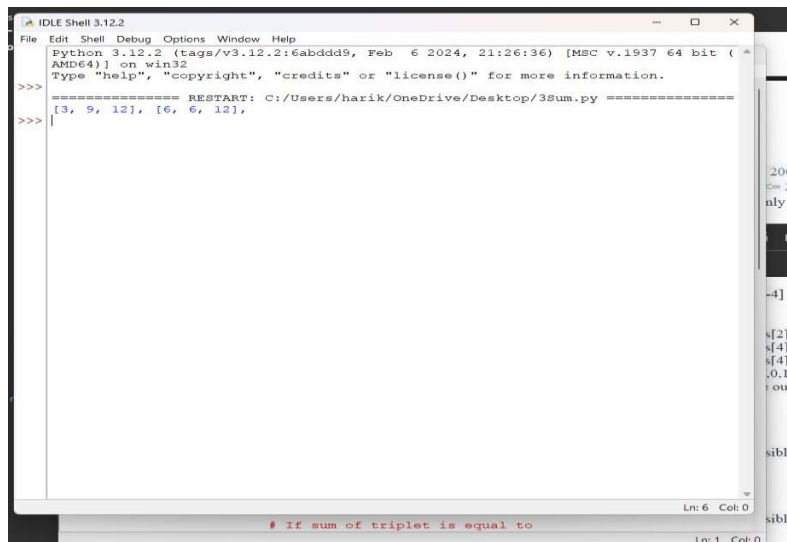

# Print all unique triplets stored in
# list.

for i in range(len(triplet)):
    print(triplet[i], end = ", ")
return 1

# Driver Code
nums = [12, 3, 6, 1, 6, 9]
n = len(nums)
Sum = 24

# Function call
if(not findTriplets(nums, n, Sum)):
    print("No triplets can be formed.")
output:

```

A screenshot of a Python IDLE Shell window. The window title is 'IDLE Shell 3.12.2'. The menu bar includes 'File', 'Edit', 'Shell', 'Debug', 'Options', 'Window', and 'Help'. The shell shows a Python 3.12.2 prompt with a restart message: 'RESTART: C:/Users/harik/OneDrive/Desktop/3Sum.py'. Below the prompt, the input '[3, 9, 12], [6, 6, 12], ' is visible. The status bar at the bottom indicates 'Ln: 6 Col: 0'.

16. 3Sum Closest

Given an integer array **nums** of length **n** and an integer **target**, find three integers in **nums** such

that the sum is closest to **target**.

Return *the sum of the three integers*.

You may assume that each input would have exactly one solution.

CODE:

```
import sys
```

```
# Function to return the sum of a
```

```
# triplet which is closest to x
```

```
def solution(arr, x):
```

```
# To store the closest sum
```

```
closestSum = sys.maxsize
```

```
# Run three nested loops each loop
```

```
# for each element of triplet
```

```
for i in range (len(arr)) :
```

```
for j in range(i + 1, len(arr)):
```

```
for k in range(j + 1, len( arr)):
```

```
# Update the closestSum
```

```

if(abs(x - closestSum) >
abs(x - (arr[i] +
arr[j] + arr[k]))):
closestSum = (arr[i] +
arr[j] + arr[k])

# Return the closest sum found
return closestSum

```

```

# Driver code
if __name__ == "__main__":

```

```

arr = [ -1, 2, 1, -4 ]
x = 1

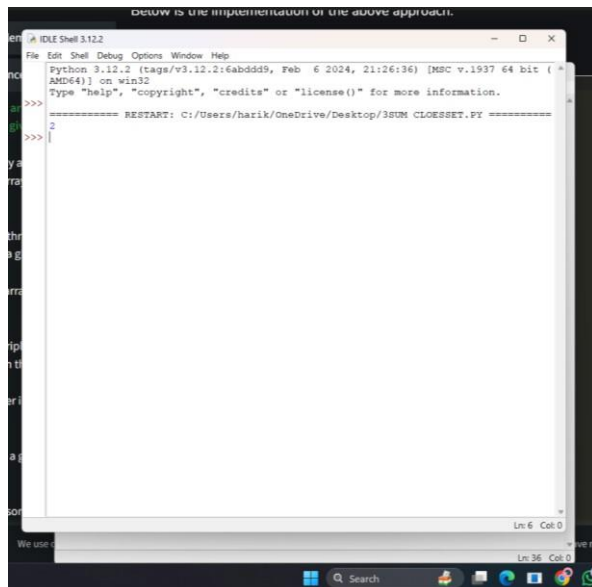

```

```

print(solution(arr, x))

```

output:

The screenshot shows a Python IDE window titled 'IDLE Shell 3.12.2'. The shell displays the following output:

```

Python 3.12.2 (tags/v3.12.2:6abddd9, Feb 6 2024, 21:26:36) [MSC v.1937 64 bit (AMD64)] on win32
Type "help", "copyright", "credits" or "license()" for more information.
>>>
>>> 2
>>> 1

```

The output indicates that the closest sum found is 1, which is the sum of the elements -1 and 2 in the array [-1, 2, 1, -4].

17. Letter Combinations of a Phone Number

Given a string containing digits from 2-9 inclusive, return all possible letter combinations that the number could represent. Return the answer in any order.

A mapping of digits to letters (just like on the telephone buttons) is given below. Note that 1 does not map to any letters.

CODE:

```
# Python3 implementation of the approach
```

```
from collections import deque
```

```
# Function to return a list that contains
```

```
# all the generated letter combinations
```

```
def letterCombinationsUtil(number, n, table):
```

```
    list = []
```

```
    q = deque()
```

```
    q.append("")
```

```
    while len(q) != 0:
```

```
        s = q.pop()
```

```
        # If complete word is generated
```

```
        # push it in the list
```

```
        if len(s) == n:
```

```
            list.append(s)
```

```
        else:
```

```
            # Try all possible letters for current digit
```

```
            # in number[]
```

```
            for letter in table[number[len(s)]]:
```

```
                q.append(s + letter)
```

```
    # Return the generated list
```

```
    return list
```

```

# Function that creates the mapping and
# calls letterCombinationsUtil
def letterCombinations(number, n):

    # table[i] stores all characters that
    # corresponds to ith digit in phone
    table = ["0", "1", "abc", "def", "ghi", "jkl",
             "mno", "pqrs", "tuv", "wxyz"]

    list = letterCombinationsUtil(number, n, table)

    s = ""
    for word in list:
        s += word + " "

    print(s)
    return

# Driver code
number = [2, 3]
n = len(number)

# Function call

20. Valid Parentheses

Given a string *s* containing just the characters '(', ')', '{', '}', '[' and ']', determine if the input string is valid.

An input string is valid if:

1. Open brackets must be closed by the same type of brackets.

- 2. Open brackets must be closed in the correct order.**
- 3. Every close bracket has a corresponding open bracket of the same type.**

CODE:

```
def areBracketsBalanced(expr):  
    stack = []  
    # Traversing the Expression  
    for char in expr:  
        if char in ["(", "{", "["]:  
            # Push the element in the stack  
            stack.append(char)  
        else:  
            # IF current character is not opening  
            # bracket, then it must be closing.  
            # So stack cannot be empty at this point.  
            if not stack:  
                return False  
            current_char = stack.pop()  
            if current_char == '(':  
                if char != ")":  
                    return False  
            if current_char == '{':  
                if char != "}":  
                    return False  
            if current_char == '[':  
                if char != "]":  
                    return False
